

COVID and Immunodeficiency

UHB patient webinar

Professor Alex Richter University of Birmingham Wednesday 8th June 2022

Immunodeficiency patients had a significantly increased vulnerability for hospitalisation and death in the first wave \otimes

So what is going on now?

Outlook has improved +++

Less hospitalization and death in Omicron wave compared to 2020

		Updated cohort				JACI 2021 UK Cohort				ort				Statistics		
	n	Age (yr, IQR)	Sex (n <i>,</i> % male)	Hospitalised (%)	Deaths	Inpatient mortality (%)	IFR (%)	n	Age (yr, IQR)	Sex (n, % male)	Hospitalis ed (n,%)	Death	Inpatient s mortality (%)	IFR (%)	p-value (hospitalisa tion)	P-value (IFR)
Primary Immunodeficiency (all)	107	45 (33-58)	57.0	16.8	3.0	16.7	2.80	60	42.0 (28.0- 58.2)	43.3	32 (53.3)	12	37.5	20.0	< 0.00001	0.0001 92
CVID	43	47 (37-61)	55.8	18.6	1.0	12.5	2.33	23	54.0 (31.8- 70.8)	39.1	13 (56.5)	8	61.5	34.8	0.001625	0.0002 51

UK OPIN Advancing Care in Primary Immunodeficiency

Direct comparison of updated cohort to Shields et al JACI 2021

CVV-AD

Infections and hospitalisation trends in Immunodeficiency patients

Immunodeficiency General population

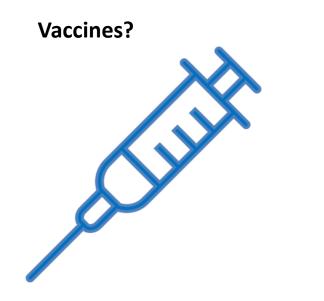

<u>Jan 21 – Jun 21</u>

- More infections and hospitalisations in the general population vs immune deficiency patients shielding making a difference
- <u>August 21- present</u>

This is reversed after relaxation of these measures

- immunodeficiency patients are still vulnerable

What has improved outcomes?

٠

٠

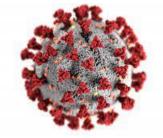

What if you don't respond to vaccination?

Is some response better than no response?

Acute treatments given early?

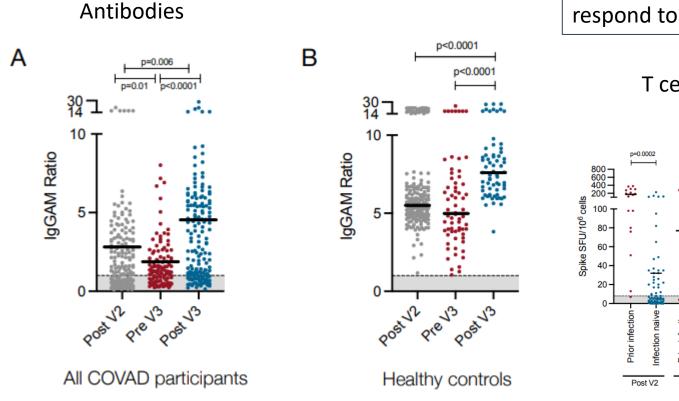

Milder virus?

Hong Kong and China experience suggests not

Vaccines

3 doses better than 2 for antibody and T cell responses

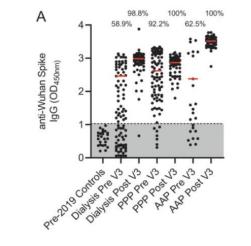

Fantastic responses in patients that don't respond to standard vaccines

T cells

Pre V3

Post V3

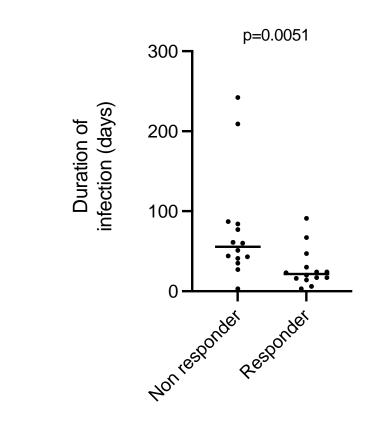

Good recognition of omicron but neutralisation not so good – antibodies work in different ways

- 61% responded post 2 doses v 76% after 3 😳 ٠
- But levels lower than health controls .

Making any antibody response either through infection or vaccination helps

	No antibody response	Antibody response			
Number	36	33			
Age	51 (37.3-62.5)	51 (35.0-61.0)			
On IVIG	88.9	87.9			
On long term antibiotics	55.6	42.4			
On Immunosuppression	22.2	18.2			
Exposures					
Prior COVID	13.9	12.1			
2 vaccine doses	94.4	100.0			
3 vaccine doses	77.8	90.9			
Omicron wave inf	ection				
Symptomatic	88.9	84.8			
Received tx	66.7	66.7			
Hospitalised	33.3	9.1			
Deaths	4.0	2			

Outcome with subsequent infection

- Looking at patients with immune impairment according to any response to vaccination
- Omicron infection usually symptomatic
- Only 2/3rds received outpatient treatment
- Hospitalisation and death higher in those that had no pre-existing antibodies

• Ability to clear the virus

ISARIC – study of patients have been hospitalised with COVID-19

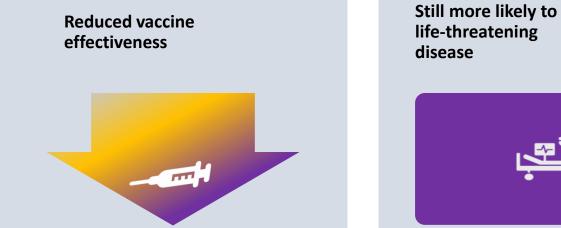

- Mortality for both immunocompetent and immunocompromised groups reduced over time.
- This reduction has been less for immunocompromised patients who remain disproportionately vulnerable

Lance Turtle and ISARIC team; manuscript in preparation

Learning to "live with COVID" if you have antibody deficiency

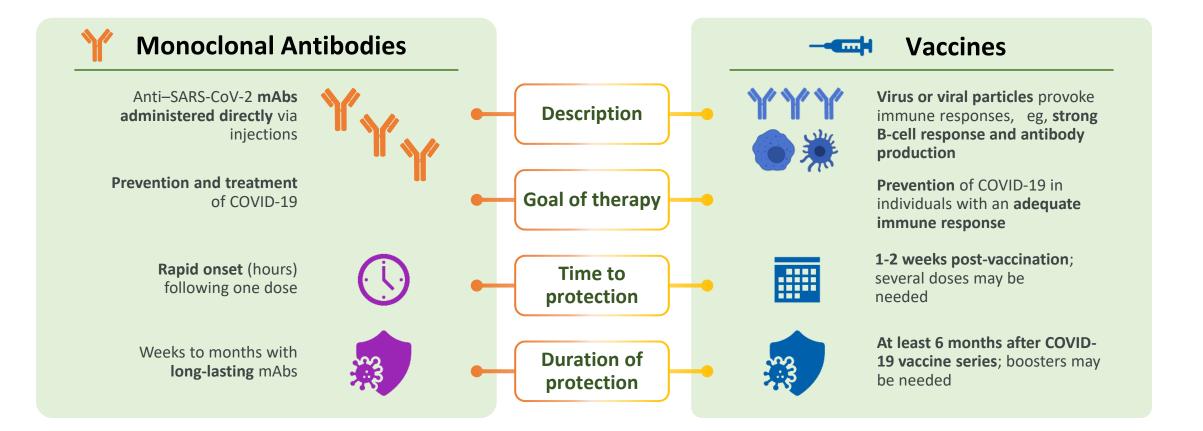

Still more likely to have severe or

May suffer prolonged illness, potentially taking months to clear the virus

> >90 days of acute infection

A role for monoclonal antibodies as a pre-exposure treatment

mAbs give vulnerable patients antibodies engineered to target SARS-CoV-2 that they cannot generate through vaccination

Concerns about current mAbs

- "Do we even need another treatment as COVID is over and only a cold"
- How well do they work against omicron data from laboratory work v real life How should they be used in immunodeficiency patients
- Who will benefit most from them
- Just not enough real life data and concern we are variant chasing
- Many countries are taking a pragmatic approach rather than waiting for data.....

Research studies coming soon

- RAPID PROTECTION Oxford led AZ Evusheld study
- PROTECT V Cambridge / Birmingham led GSK Sotrovimab
- United Kingdom COVID 19 Immune Suppressed Disease Consortium (UK- CISD)

The future

- Management and treatment of COVID likely to be given back to NHS
 - Hopefully allow personalised decision making of risk as we usually do
- Pre-exposure prophylaxis
- Check with your clinicians about what studies may be open to you
- Continue to manage the personal risk of COVID and all other infections

Managing the risk of COVID (or any) infection

Prevention of infection

Early recognition and treatment

High quality masks

Speak to your workplace about your risk and reasonable adjustment

Covid Medicine Delivery Unit (CMDU)

Limit time in crowded spaces especially inside If have to – wear a mask

Try and avoid individuals you know are unwell

Get all vaccinations Encourage family members to get vaccinated

Test if any symptoms for early diagnosis Ask family to test if visiting

NHS
